Z_{RLC} is the RLC circuit impedance in ohms (Ω), $\omega = 2\pi f$ is the angular frequency in rad/s, f is the frequency in hertz (Hz), R is the resistance in ohms (Ω), L is the inductance in henries (H), C is the capacitance in farads (F), Q is the quality factor of a parallel RLC circuit (dimensionless), ω_0 is the resonant angular frequency in radian per second (rad/s), f_0 is the ...

The zero-sequence current drawn by a bank is the zero-sequence voltage divided by the zero-sequence impedance: $I_0 = V_0 / Z_0$. Severe voltage unbalance can result when one phase voltage is opened upstream (usually from a blown fuse or

a tripped single-phase recloser). In this case, the zero-sequence voltage equals the line-to-neutral voltage.

Where and Why Do We Use Grounding Transformer?

Which of the following are reasons why short-circuit studies involve calculating a bolted 3-phase fault condition? a. Three phases bolted together create a near zero impedance connection. b. A "worst case" (highest current) condition that results in maximum 3-phase thermal and mechanical stress in the system is established. c.

To avoid this appearance of this dangerous, exposed shock hazard voltage, the equipment grounding conductor must present a low impedance path from the stricken frame to the zero potential ground junction. The impedance should also be sufficiently low enough to accept the full magnitude of the line-to-ground fault current without creating an ...

If a source is assigned a time-dependent value, the time-zero value is used for dc analysis. There are five independent source functions: pulse, exponential, sinusoidal, piece-wise linear, and single-frequency FM. If parameters other than source values are omitted or set to zero, the default values shown are assumed.
