Deep reinforcement learning combines artificial neural networks with a reinforcement learning architecture that enables software-defined agents to learn the best actions possible in virtual environment in order to attain their goals. That is, it unites function approximation and target optimization, mapping state-action pairs to expected rewards.

Recent paper from Google Brain team, What Matters In On-Policy Reinforcement Learning? A Large-Scale Empirical Study, tackles one of the notoriously neglected problems in deep Reinforcement Learning (deep RL). I believe this is a pain point both for RL researchers and engineers: Out of dozens of RL algorithm hyperparameters, which choices are actually important for the performance of the agent?
